### 5.0 Learning Objectives

After studying this unit student should be able to learn:

- Define Application Resources
- List different types of resources
- Understand resource directory hierarchy within android project
- How resources are stored
- Access user resources and system resources programmatically.

### 5.1 Introduction

Resources are the additional files and static content that your code uses, such as bitmaps, layout definitions, user interface strings, animation instructions, and more.

You should always externalize app resources such as images and strings from your code, so that you can maintain them independently. You should also provide alternative resources for specific device configurations, by grouping them in specially-named resource directories. At runtime, Android uses the appropriate resource based on the current configuration. For example, you might want to provide a different UI layout depending on the screen size or different strings depending on the language setting.

Once you externalize your app resources, you can access them using resource IDs that are generated in your project's R class. This document shows you how to group your resources in your Android project and provide alternative resources for specific device configurations, and then access them from your app code or other XML files. The well-written application accesses its resources programmatically instead of hard coding them into the source code. This is done for a variety of reasons. Storing application resources in a single place is a more organized approach to development and makes the code more readable and maintainable. Externalizing resources such as strings makes iteasier to localize applications for different languages and geographic regions.

#### 5.2 What are resources?

All Android applications are composed of two things: functionality (code instructions) anddata (resources). The functionality is the code that determines how your application behaves. This includes any algorithms that make the application run. Resources include textstrings, images and icons, audio files, videos, and other data used by the application. Android resource files are stored separately from the java class files in the Android project. Most common resource types are stored in XML. You can also store raw data files

### **5.3 Resource Directory Hierarchy**

Resources are organized in a strict directory hierarchy within the Android project. All resourcesmust be stored under the /res project directory in specially named subdirectoriesthat must be lowercase. Different resource types are stored in different directories. The resource sub-directories generated when you create an Android project are shown in below.

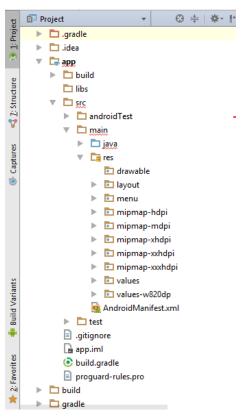

Figure-60: Resource Hierarchy

Each resource type corresponds to a specific resource subdirectory name. For example, all graphics are stored under the /res/drawable directory structure. Resources can be furtherorganized in a variety of ways using even more specially named directory qualifiers.

For example, the /res/drawable-hdpi directory stores graphics for high-density screens, the /res/drawable-ldpi directory stores graphics for low-density screens, and the/res/drawable-mdpi directory stores graphics for medium-density screens. If you had agraphic resource that was shared by all screens, you would simply store that resource in the/res/drawable directory.

### **5.4 Resource Value Types**

Android applications rely on many different types of resources—such as text strings, graphics, and color schemes—for user interface design.

These resources are stored in the /res directory of your Android project in a strict (butreasonably flexible) set of directories and files. All resources filenames must be lowercaseand simple (letters, numbers, and underscores only).

The resource types supported by the Android SDK and how they are stored within the project are shown in table below

Resource Type	Directory	Filename	XML Tag
Strings	/res/values/	strings.xml	<string></string>
StringPluralization	/res/values/	strings.xml	<plurals>, <item></item></plurals>
Arrays ofStrings	/res/values/	strings.xml	<string-array>,<item></item></string-array>
Booleans	/res/values/	bools.xml	<bool></bool>
Colors	/res/values/	Colors.xml	<color></color>
Color StateLists	/res/color/	Examples include buttonstates.xml indicators.xml	<selector>, <item></item></selector>
Dimensions	/res/values/	Dimens.xml	<dimen></dimen>
Integers	/res/values/	integers.xml	<integer></integer>

Resource Type	Directory	Filename	XML Tag
Arrays ofIntegers	/res/values/	integers.xml	<integer-array>,<item></item></integer-array>
Mixed-TypeArrays	/res/values/	Arrays.xml	<array>, <item></item></array>
SimpleDrawables	/res/values/	drawables.xml	<drawable></drawable>
Graphics	/res/drawable/	Examples include	Supported graphics
		icon.png logo.jpg	files
			or drawable definition
			XML files such
			asshapes.
TweenedAnimations	/res/anim/	Examples include	<set>, <alpha>,</alpha></set>
		fadesequence.xml	<scale>, <translate>,</translate></scale>
		spinsequence.xml	<rotate></rotate>
Frame-by-Frame	/res/drawable/	Examples include	<animation-list>,</animation-list>
Animations		sequence1.xml	<item></item>
		sequence2.xml	
Menus	/res/menu/	Examples include	<menu></menu>
		mainmenu.xml	
		helpmenu.xml	
XML Files	/res/xml/	Examples include	Defined by the
		data.xml	developer
		data2.xml	
Raw Files	/res/raw/	Examples include	Defined by the
		jingle.mp3	developer
		somevideo.mp4	
		helptext.txt	
Layouts	/res/layout/	Examples include	Varies. Must be a
		main.xml	layoutcontrol.
		help.xml	
Styles andThemes	/res/values/	styles.xml	<style></th></tr><tr><th></th><th></th><th>themes.xml</th><th></th></tr></tbody></table></style>

Table-17

## 5.5 Storing Different Resource Value Types

#### **Storing Simple Resource Types Such as Strings**

Simple resource value types, such as strings, colors, dimensions, and other primitives, arestored under the /res/values project directory in XML files. Each resource file underthe /res/values directory should begin with the following XML header:

<?xml version="1.0" encoding="utf-8"?>

Next comes the root node <resources> followed by the specific resource element typessuch as <string> or <color>. Each resource is defined using a different element name. Although the XML file names are arbitrary, the best practice is to store your resourcesin separate files to reflect their types, such as strings.xml, colors.xml, and so on. However, there's nothing stopping the developers from creating multiple resource files for agiven type, such as two separate xml files called bright\_colors.xml andmuted\_colors.xml, if they so choose.

#### Storing Graphics, Animations, Menus, and Files

In addition to simple resource types stored in the /res/values directory, you can alsostore numerous other types of resources, such as animation sequences, graphics, arbitraryXML files, and raw files. These types of resources are not stored in the /res/values directory, but instead stored in specially named directories according to their type. For example, you can include animation sequence definitions in the /res/anim directory. Makesure you name resource files appropriately because the resource name is derived from the filename of the specific resource. For example, a file called flag.png in the/res/drawable directory is given the name R.drawable.flag.

# 5.6 Accessing Resource Programmatically

When android application is compiled, a R class gets generated, which contains resource IDs for all the resources available in your res/ directory. You can use R

class to access that resource using sub-directory and resource name or directly resource ID.

During your application development you will need to access defined resources either in your code, or in your layout XML files. Following section explains how to access your resources in both the scenarios.

**Example-1:** To access res/drawable/myimage.png and set an ImageView you will use following code –

```
ImageViewimageView = (ImageView) findViewById(R.id.myimageview);
imageView.setImageResource(R.drawable.myimage);
```

Here first line of the code make use of R.id.myimageview to get ImageView defined with id myimageview in a Layout file. Second line of code makes use of R.drawable.myimage to get an image with name myimage available in drawable subdirectory under /res.

**Example-2:** Consider next example where res/values/strings.xml has following definition:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
<string name="hello">Hello, World!</string>
</resources>
```

Now you can set the text on a TextView object with ID msg using a resource ID as follows:

```
TextViewmsgTextView = (TextView) findViewById(R.id.msg);
msgTextView.setText(R.string.hello);
```

**Example-3:**Consider a layout res/layout/activity\_main.xml with the following definition

```
<?xml version="1.0" encoding="utf-8"?>
```

```
<LinearLayoutxmlns:android="http://schemas.android.com/apk/res/android"</p>
android:layout_width="fill_parent"
android:layout_height="fill_parent"
android:orientation="vertical" >
<TextViewandroid:id="@+id/text"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:text="Hello, I am a TextView" />
<Button android:id="@+id/button"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:text="Hello, I am a Button" />
</LinearLayout>
This application code will load this layout for an Activity, in the onCreate() method as
follows:
```

```
public void onCreate(Bundle savedInstanceState) {
super.onCreate(savedInstanceState);
setContentView(R.layout.activity_main);
}
```

#### **Accessing Resources in XML Layout**

Consider the following resource XML res/values/strings.xml file that includes a color resource and a string resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
<color name="opaque_red">#f00</color>
<string name="hello">Hello!</string>
</resources>
```

Now you can use these resources in the following layout file to set the text color and text string as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<EditTextxmlns:android="http://schemas.android.com/apk/res/android"
android:layout_width="fill_parent"
android:layout_height="fill_parent"
android:textColor="@color/opaque_red"
android:text="@string/hello" />
```

### 5.7 Referencing System Resources

You can access system resources in addition to your own resources. The android package contains all kinds of resources, which you can browse by looking in the android. R subclasses. Here you find system resources for

- Animation sequences for fading in and out
- Arrays of email/phone types (home, work, and such)
- Standard system colors
- Dimensions for application thumbnails and icons
- Many commonly used drawable and layout types
- Error strings and standard button text
- System styles and themes

You can reference system resources the same way you use your own; set the package nameto android. For example, to set the background to the system color for darker gray, youset the appropriate background color attribute to @android:color/darker\_gray.

You can access system resources much like you access your application's resources. Insteadof using your application resources, use the Android package's resources under theandroid.R class.

#### **Check your progress-1**

- a) All Android applications is composed of \_\_\_\_\_
  - (A) Functionality (B) Data (C) Both A and B (D) Neither A nor B
- b) You should always externalize app resources from your code, so that you can maintain them independently (True/False)
- c) You can use R class to access that resource using sub-directory and resource name or directly resource ID. (True/False)
- d) You cannot store resources, such as animation sequences, graphics, arbitrary XML files, and raw files. (True/False)
- e) All resources filenames must be in uppercase and simple (True/False)
- f) Different resource types are stored in different directories (True/False)
- g) You can access system resources much like you access your application's resources. (True/False)

### 5.8 Let us sum up

Android applications rely on various types of resources, including strings, string arrays, colors, dimensions, drawable objects, graphics, animation sequences, layouts, styles, andthemes. Resources can also be raw files. Many of these resources are defined with XML and organized into specially named project directories. Both default and alternativeresources can be defined using this resource hierarchy.

Resources are compiled and accessed using the R.java class file, which is automatically generated when the application resources are compiled. Developers access application and system resources programmatically using this special class.

# 5.9 Check your Progress: Possible Answers

1-a) Both A and B 1-b) True 1-c) True

1-d) False 1-e) False 1-f) True

1-g) True

### **5.11 Assignment**

- What are resources?
- Explain Resource Directory Hierarchy
- How can we reference the system resources?
- Explain with example how can we access resource programmatically?

# 5.12 Activity

 Create String Resource for Title and Welcome message for Main Activity and use it at design time and programmatically to set at runtime.
